# Contents

1. Accelerator Production of Tritium (APT) Project
  - Measurements of  $\beta=0.64$ , 5-cell 700 MHz elliptical cavities
2. Advanced Accelerator Applications (AAA) Project (Transmutation of Nuclear Waste)
  - Measurements of  $\beta=0.29$  (ANL) and 0.175 (LANL) spoke cavities
3. High- $T_c$  materials study for RF cavities
  - Measurements of  $\text{MgB}_2$  RF surface resistance and its dependence on higher gradients

# 1. Accelerator Production of Tritium (APT) Project

- Purpose: Replenish Tritium Inventory for Nuclear Weapons (3 kg/year)
- Method: Using spallation neutrons made by proton accelerator, split Lithium into Tritium and Helium.

# 700 MHz SC Section Specs

$\beta$	0.64	0.82
$E_{\text{acc}}$ (MV/m)	5.5	4.1 (6.4)
Real estate $E_{\text{acc}}$	1.54	1.26 (1.89)
$E_{\text{peak}}$	19.1	12.7 (19.1)
No. Cavities	90	312
Aperture (cm)	13	16
Aperture/(rms-beam size)	35	45
Thermal load @ 1.9 K (kW)	2.0	6.1 (9.2)

Numbers in parentheses are for 1.7 GeV case

# APT $\beta = 0.64$ , 700 MHz, 5-Cell Cavity

Cavity length : 116 cm  
Cell diameter : 40 cm  
Beam aperture : 13 cm  
 $E_p/E_{acc} = 3.38$   
 $H_p/E_{acc} = 69.6 \text{ Oe}/(\text{MV}/\text{m})$

# Facilities for SRF Activities at LANSCE

2600 ft<sup>2</sup> Class-100 Clean room

Ultra-pure water system with 1500 gallon storage tank

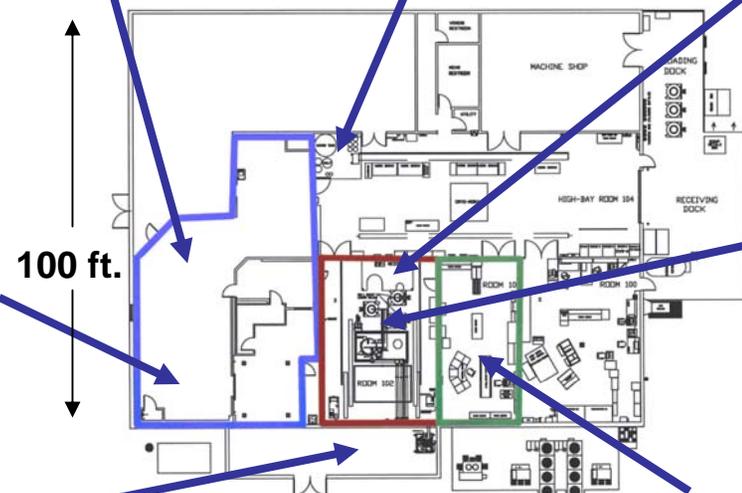

2 Inserts for 38-inch, 10 feet deep cryostat

High-pressure rinse in a clean room.

← 140 ft. →

Cryostat with movable radiation shield

4/8/05 LA-UR-05-2593

Pumps to pump down the cryostat to < 2 K

ANL Beam & Application Seminar Control, tuning

***This 2,600 ft<sup>2</sup> clean room is divided into class-1,000 and class-100 clean rooms for assembling SC cavities.***

Behind the curtain is a 13 m x 7 m class 100 area with ceiling height of 10 feet.

The other areas are class 1000 and ceiling height of 8 feet.

***High-pressure rinsing system. While the cavity is rotating on the turn table at ~ 30 rpm, water jets at 1,000-1500 psi move up and down automatically and rinse off the particles and chemical residues from the inner surface of the cavity.***

*Ultrasonic cleaning system to degrease, clean, and rinse the components for SC cavities and power couplers in the clean room. (three 90-gallon baths with 40-kHz oscillators)*

*Ultra-pure water system  
that can produce 2,000  
gallons per day of de-  
ionized water with a  
resistivity (purity) of ~18  
M $\Omega$ ·cm.  
Shown in the center is a  
1,500-gallon storage tank.*

# Two 38-inch diameter cryostat inserts

# Cavity Performance Measurement

- $Q_0$  (Cavity unloaded Q) versus  $E_{acc}$  (accelerating gradient, MV/m)

- Basic parameters

$$Q_0 = G / R_s$$

G: Geometrical Factor, constant dependent on the cavity shape

$$R_s = R_{BCS} + R_{res}$$

$R_s$ : RF Surface Resistance

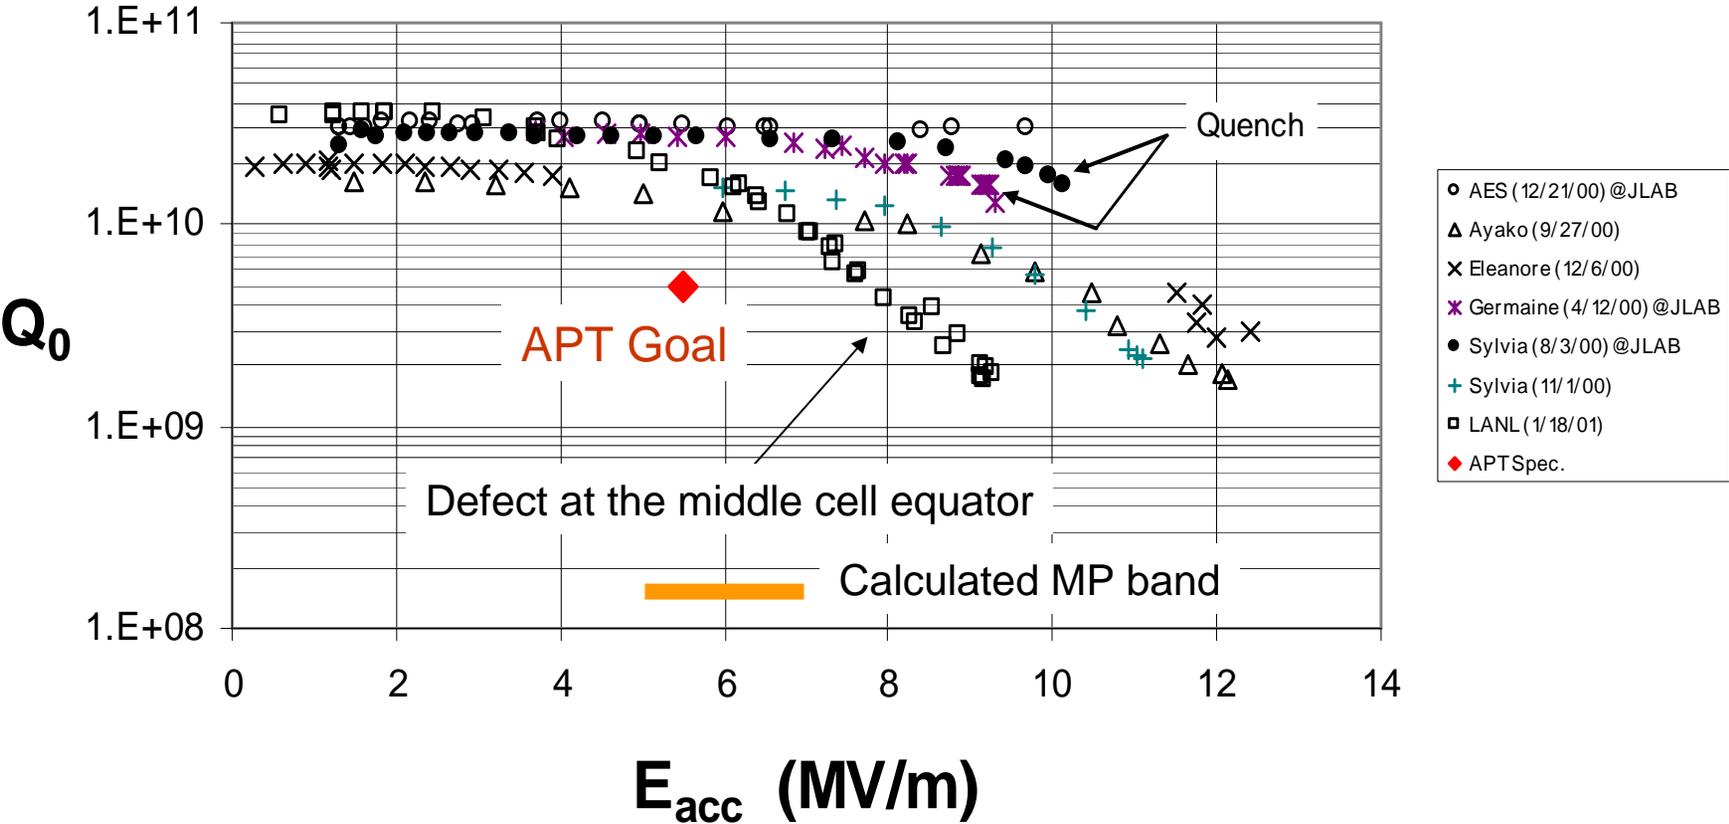

$$R_{BCS} = A \cdot \frac{f^2}{T} \cdot \exp\left(-\frac{\Delta}{k_B T_c} \cdot \frac{T_c}{T}\right)$$

$$R_{res} = R_{res}(H_{rf}) + R_{fl}(H_{rf}, H_{ext}, T)$$

# Results of 6 Prototype Cavities at 2 K. Defects, field emission and MP? limited performance.

$\beta=0.64$

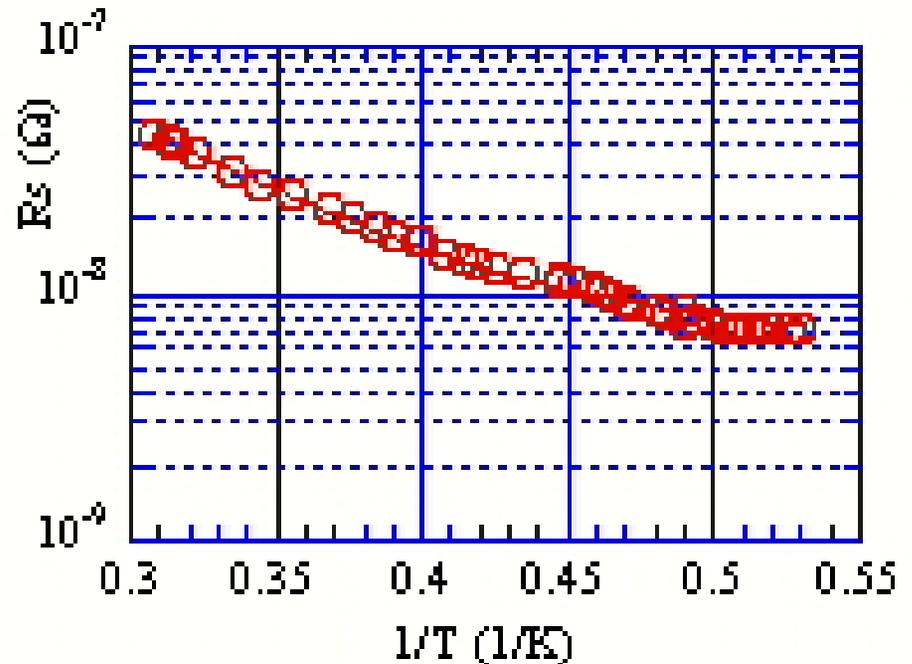

Best results of all the APT 5-cell cavities (up to 1/29/01)

An example of  
the temperature  
dependence of  
 $R_s$

Cavity: Sylvia

$R_s = a*1/T*\exp(-b*1/T)+R_{res}$		
	Value	Error
a	3.9804e-05	4.4326e-06
b	18.734	0.35986
$R_{res}$	6.4452e-09	1.9664e-10
Chisq	1.5188e-17	NA
R	0.99857	NA

# Comparison with TESLA Cavities

- Difference of  $E_p/E_{acc}$  and  $H_p/E_{acc}$ .

$$\frac{(E_p/E_{acc})_{APT}}{(E_p/E_{acc})_{TESLA}} = \frac{3.38}{2.0} = 1.69$$

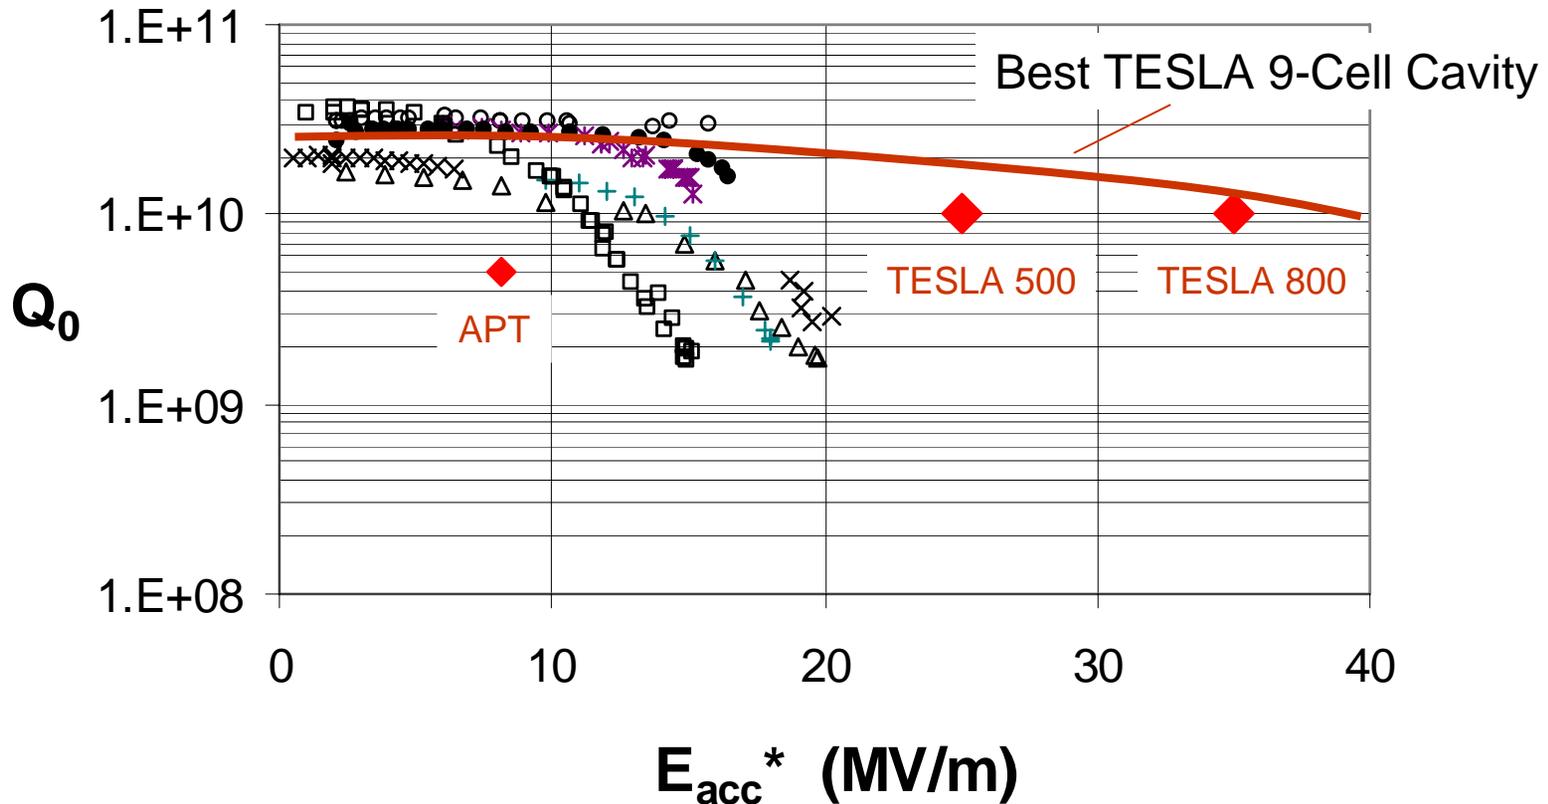

APT cavity shape is not well optimized!

$$\frac{(H_p/E_{acc})_{APT}}{(H_p/E_{acc})_{TESLA}} = \frac{69.6}{42.6} = 1.63$$

- Difference of  $\beta$ . APT(0.64) vs. TESLA (1).
  - It might be more susceptible to multipacting due to the squeezed shape

# Comparison with TESLA Cavities

APT results were converted to TESLA equivalent numbers for comparison.

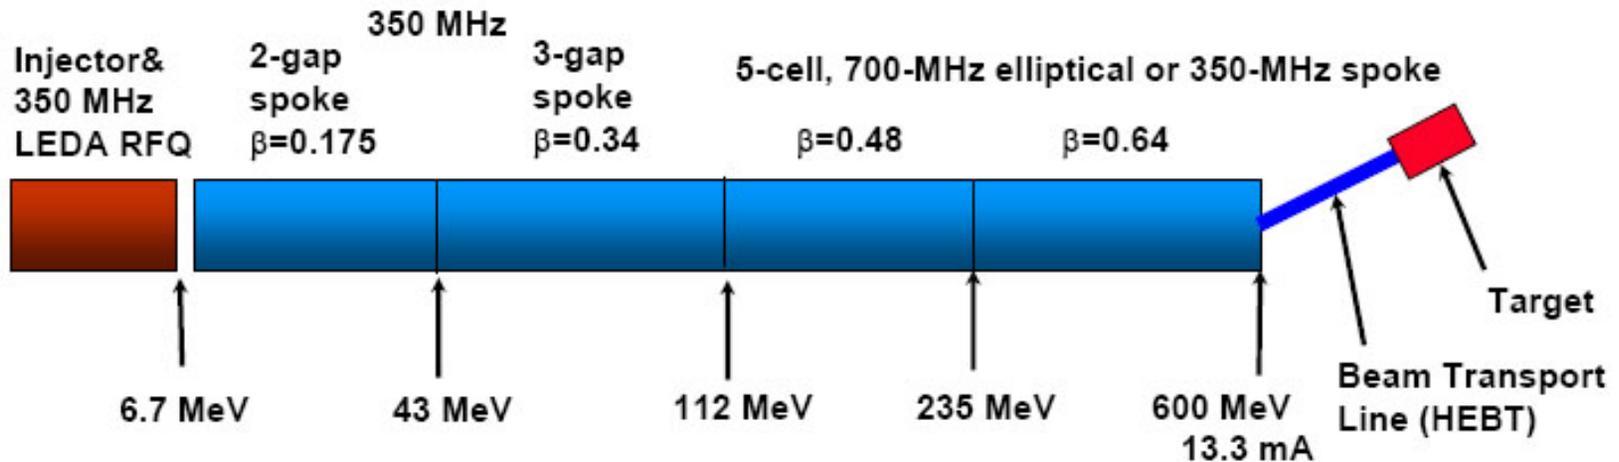

$E_{acc}^*$ :  $H_p/E_{acc} = 42.6$  was used.

# Issues that need to be addressed

- The APT Goal was achieved, but we need to achieve higher gradients for future machines to further reduce costs.
- $Q_0$  drops at medium and high gradient due to Multipacting and Field emission.
- Measures to take
  - MP free design of the cavity with MP codes.
  - Thermometry and other diagnostics for detecting heating spots to localize and identify the problem.
  - Improve contamination control during assembly to reduce field emission due to migrated particles.

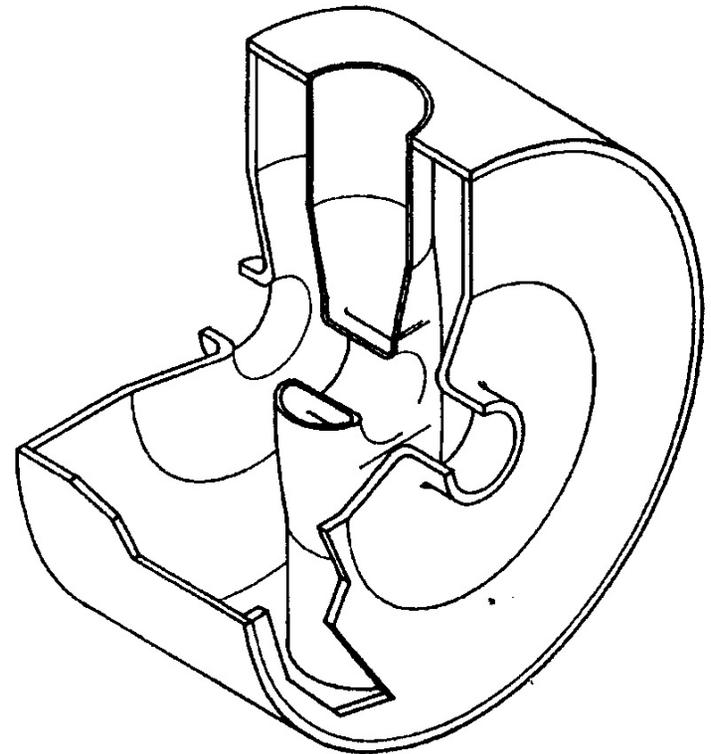

## 2. Advanced Accelerator Applications (AAA) Project

- Purpose: Transmutation of Nuclear Waste, i.e., reduce life of nuclear waste by about 2 orders of magnitude to <500 years.
- Method: Accelerator-Driven System.

# Spoke Cavity Development for Low-Energy Sections of Proton Linacs

- Studies have been carried out at ANL since late '80s (Jean Delayen, Ken Shepard)
- Advantages over elliptical cavities
  - Compact ( $\sim 1/2$  of elliptical)
  - Can be operated at 4 K
  - Mechanically stable
- One spoke cavity loaned from ANL was evaluated at LANL and the result was promising

# Tests on ANL $\beta = 0.29$ , 340 MHz, 2-gap Spoke Cavity

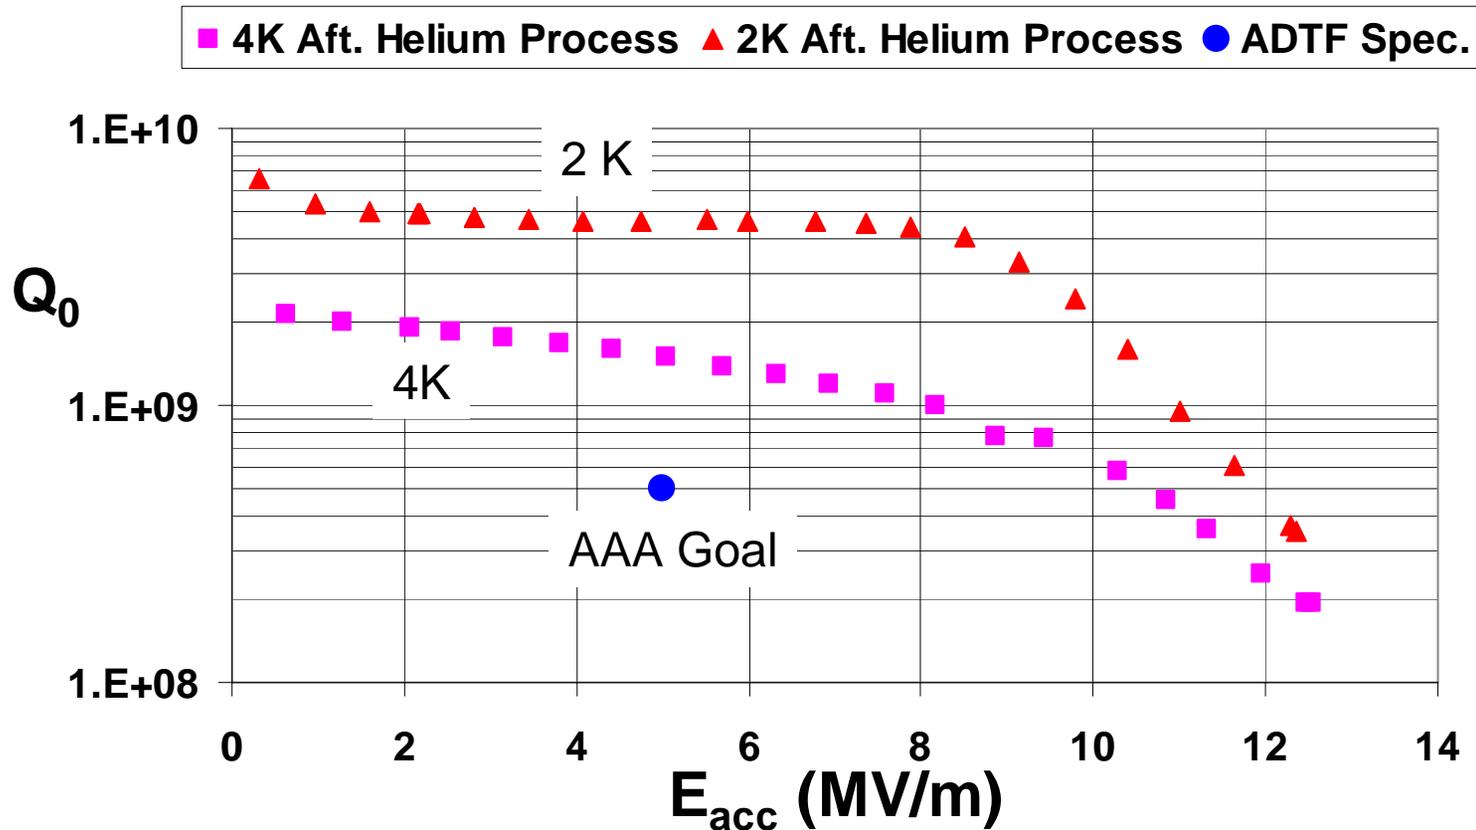

Cell diameter : 44.2 cm  
Cavity length : 30 cm  
Beam aperture : 3.2 cm

$$E_p/E_{acc} : 3.18$$

$$H_p/E_{acc} : 85 \text{ Oe/MV/m}$$

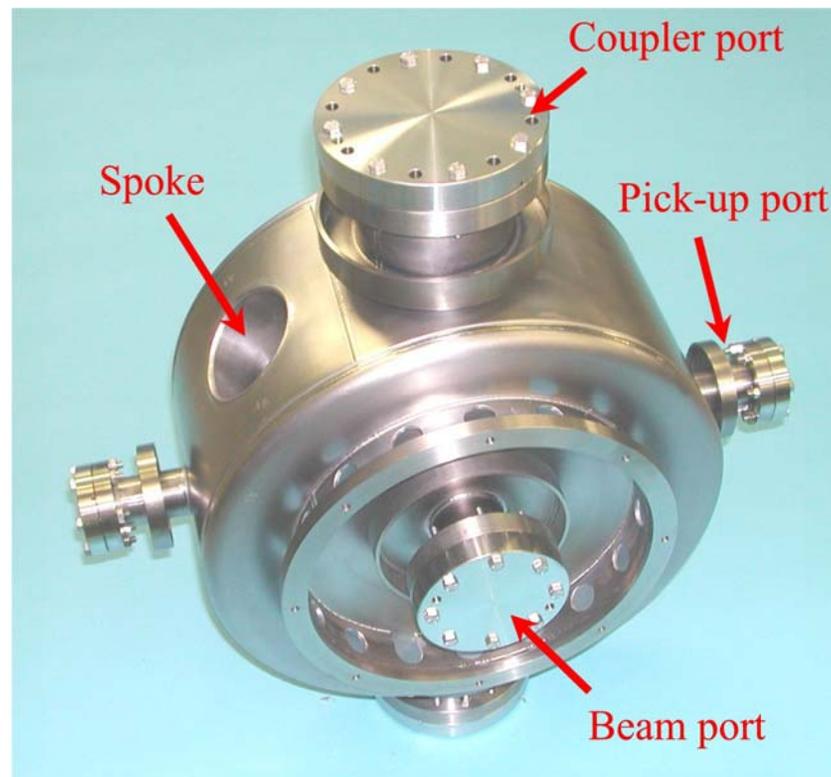

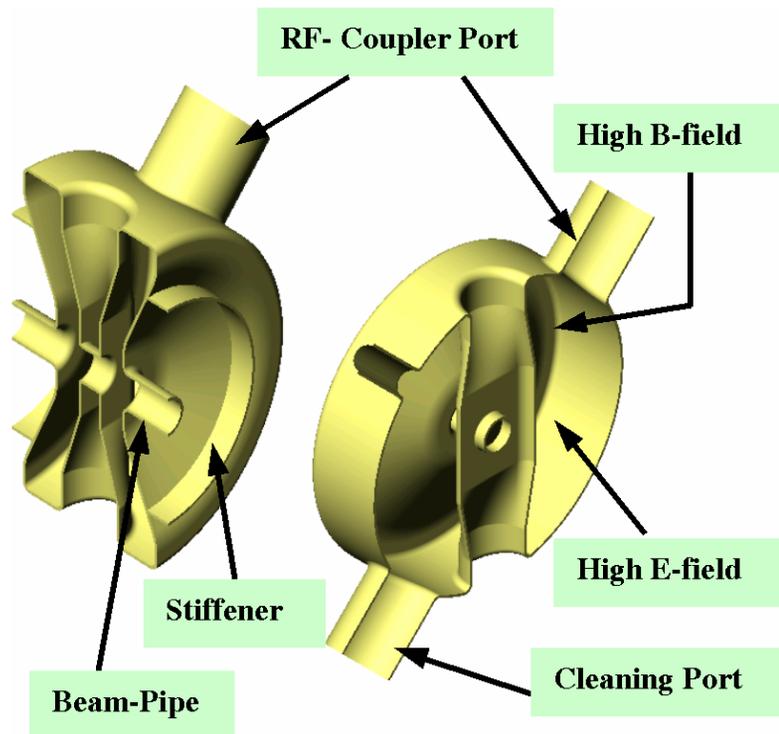

# Vertical Test Results of ANL $\beta=0.29$ , 340 MHz, 2-Gap Spoke Cavity

ANL  $b=0.29$  spoke cavity Q vs. Eacc

# AAA $\beta=0.175$ , 350-MHz, 2-Gap, Spoke Cavity

Two cavities were fabricated at ZANON, Italy.

Cell diameter : 39.2 cm  
Cavity length : 20 cm  
Beam aperture : 5 cm

$$E_p/E_{acc} : 2.82$$

$$H_p/E_{acc} : 69 \text{ Oe/MV/m}$$

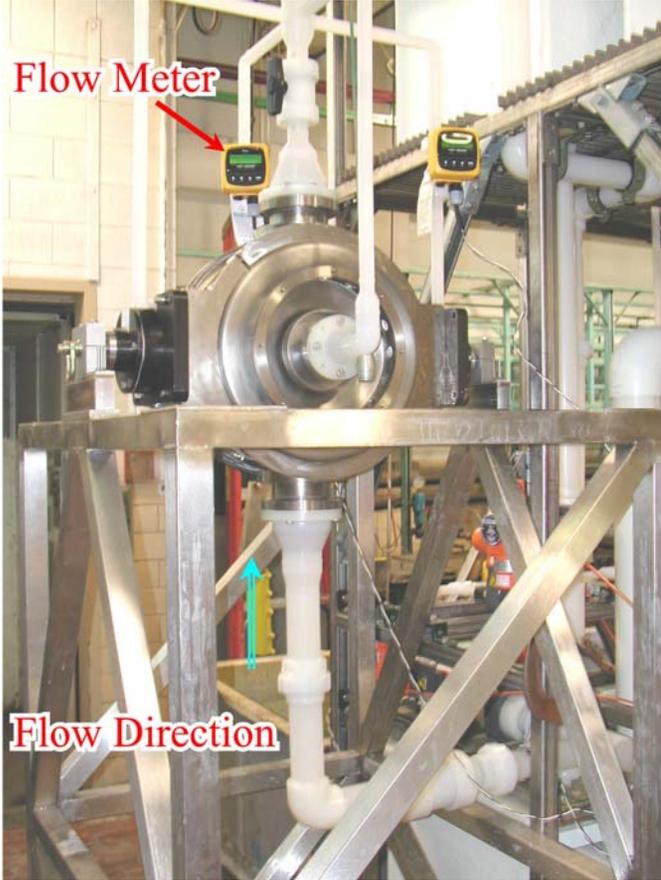

# Buffered Chemical Polishing (BCP) Improvement

$\text{HF}:\text{HNO}_3:\text{H}_3\text{PO}_4=1:1:2$  by volume at  $< 15\text{ }^\circ\text{C}$

EZ02

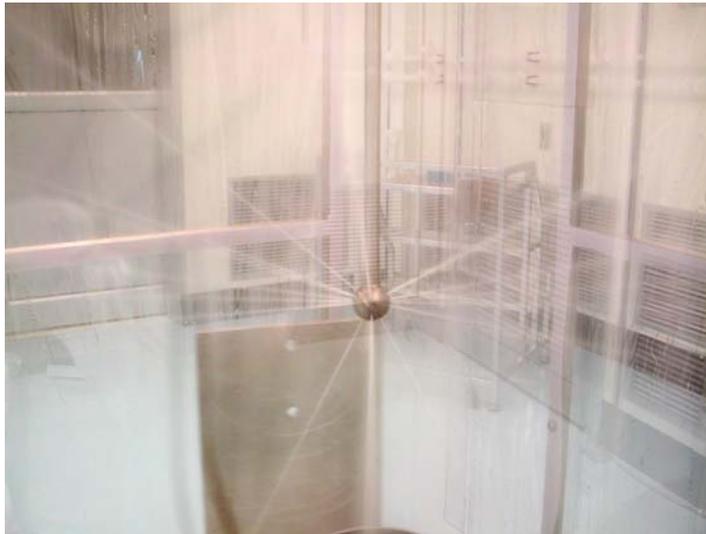

EZ01

# High Pressure Rinsing (HPR) Procedure

- Ultra-pure water
- Pressure 1000-1200 psi (69 – 83 bar)
- At 4 positions
  - beam port 1 (10 min.)
  - radial port 1 (10 min.)
  - beam port 2 (10 min.)
  - radial port 2 (20 min.)
- Sweep speed
  - Up ~ 4 mm/s
  - Down ~ 7.5 mm/s
- Table rotation ~ 23 rpm

## Nozzle made by SST

Outer diameter: 31.75 mm

Holes: 457  $\mu\text{m}$ -diam., 3.81 mm long

No. of holes: 21

11 different angles to cover all the surfaces

# Assembly in the Clean Room

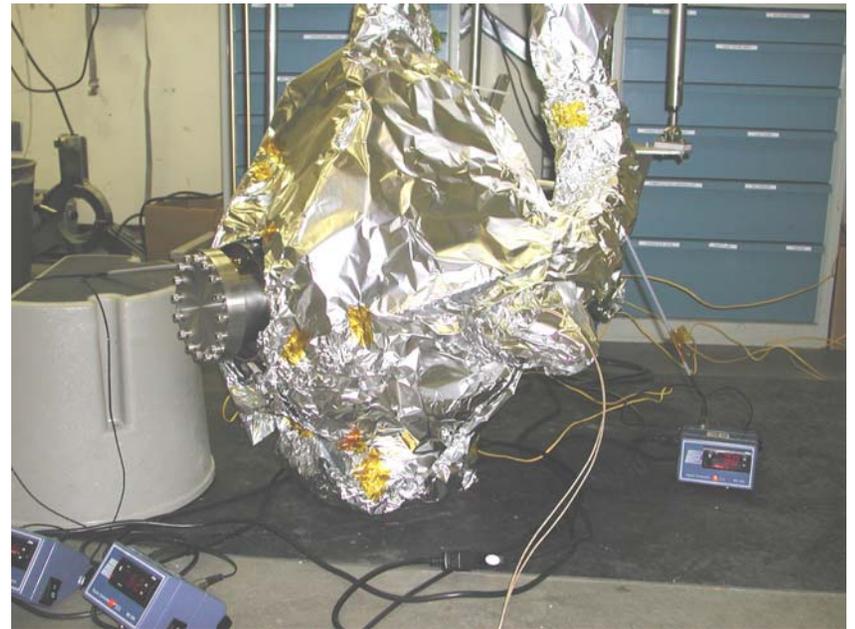

- Clean room class 100
- For tapped holes, anti-seize grease is used
- For through holes, SS bolts and silicon-bronze nuts are used.
- Nominally, all the flanges are Conflat, but indium seals were used to attach Nb blank flanges on the large radial ports for the vertical tests.
- Special polyethylene cover was made to attach indium on the flat surface inside of Conflat knife edge.

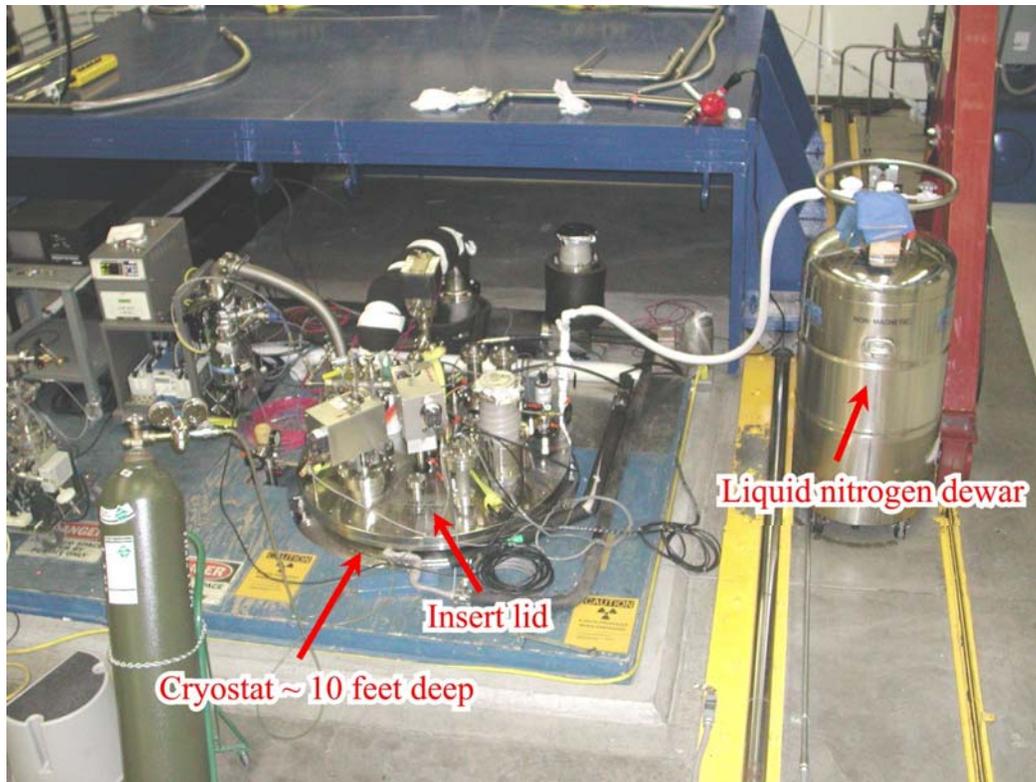

# Set Up on the Insert and Baking

Baking at  $\sim 110$  °C for  $\sim 2$  days  
Indium  $< 80$  °C

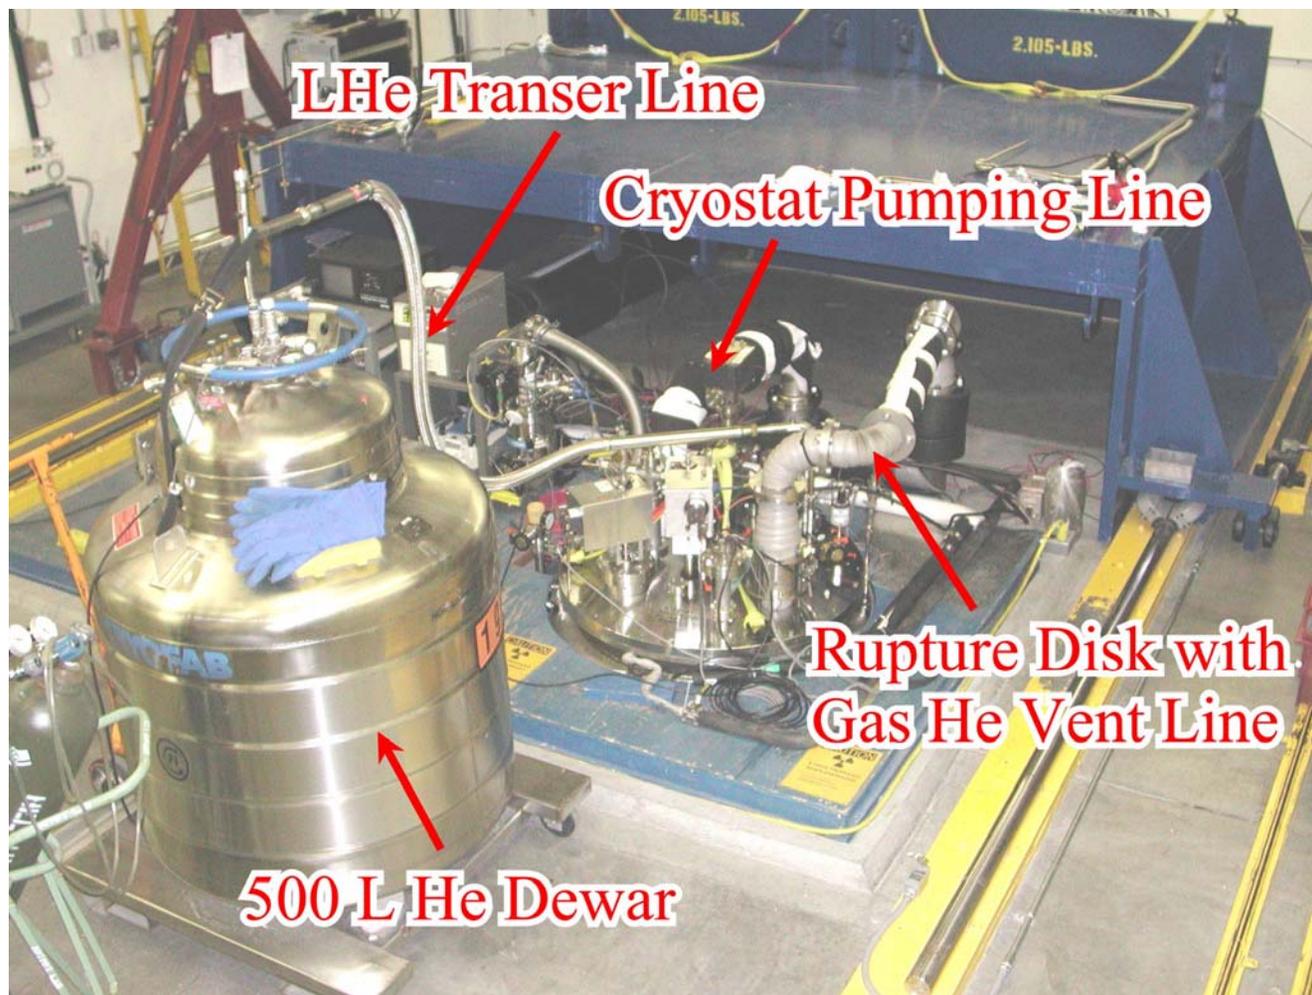

# Indirect Pre-Cooling with Liquid Nitrogen

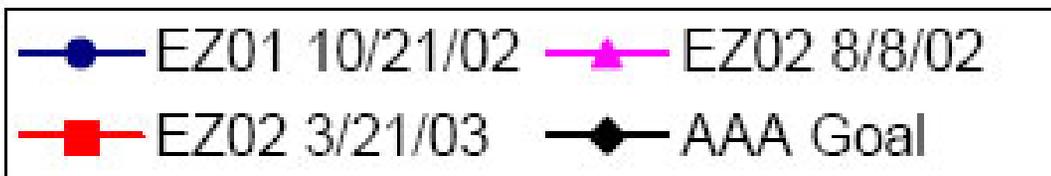

- Fill the vacuum-insulated layer between inner and outer vessel with LN
- This operation is carried out one day before LHe transfer
- When LHe transfer starts, the cavity temperature is  $\sim 250$  K

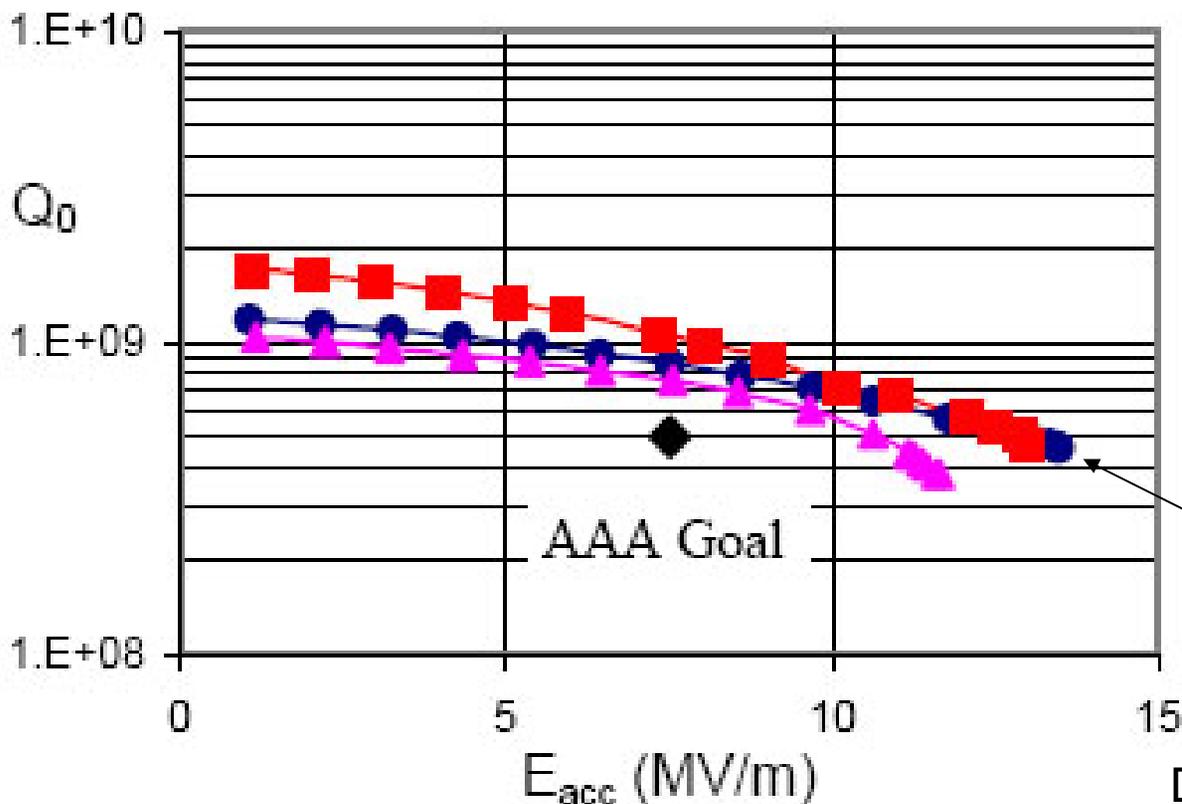

# Helium Transfer and Testing

# Vertical Test Results of LANL $\beta=0.175$ , 350-MHz, Spoke Cavities

With Nb blank flanges on large radial ports

The second EZ02 test was done after disassembly and high-pressure rinse.

$$E_{acc, max} = 13.5 \text{ MV/m}$$

$$E_{p, max} = 38.0 \text{ MV/m}$$

$$H_{p, max} = 994 \text{ Oe}$$

Details in PAC03 Proceedings.

# Some questions that need to be answered.

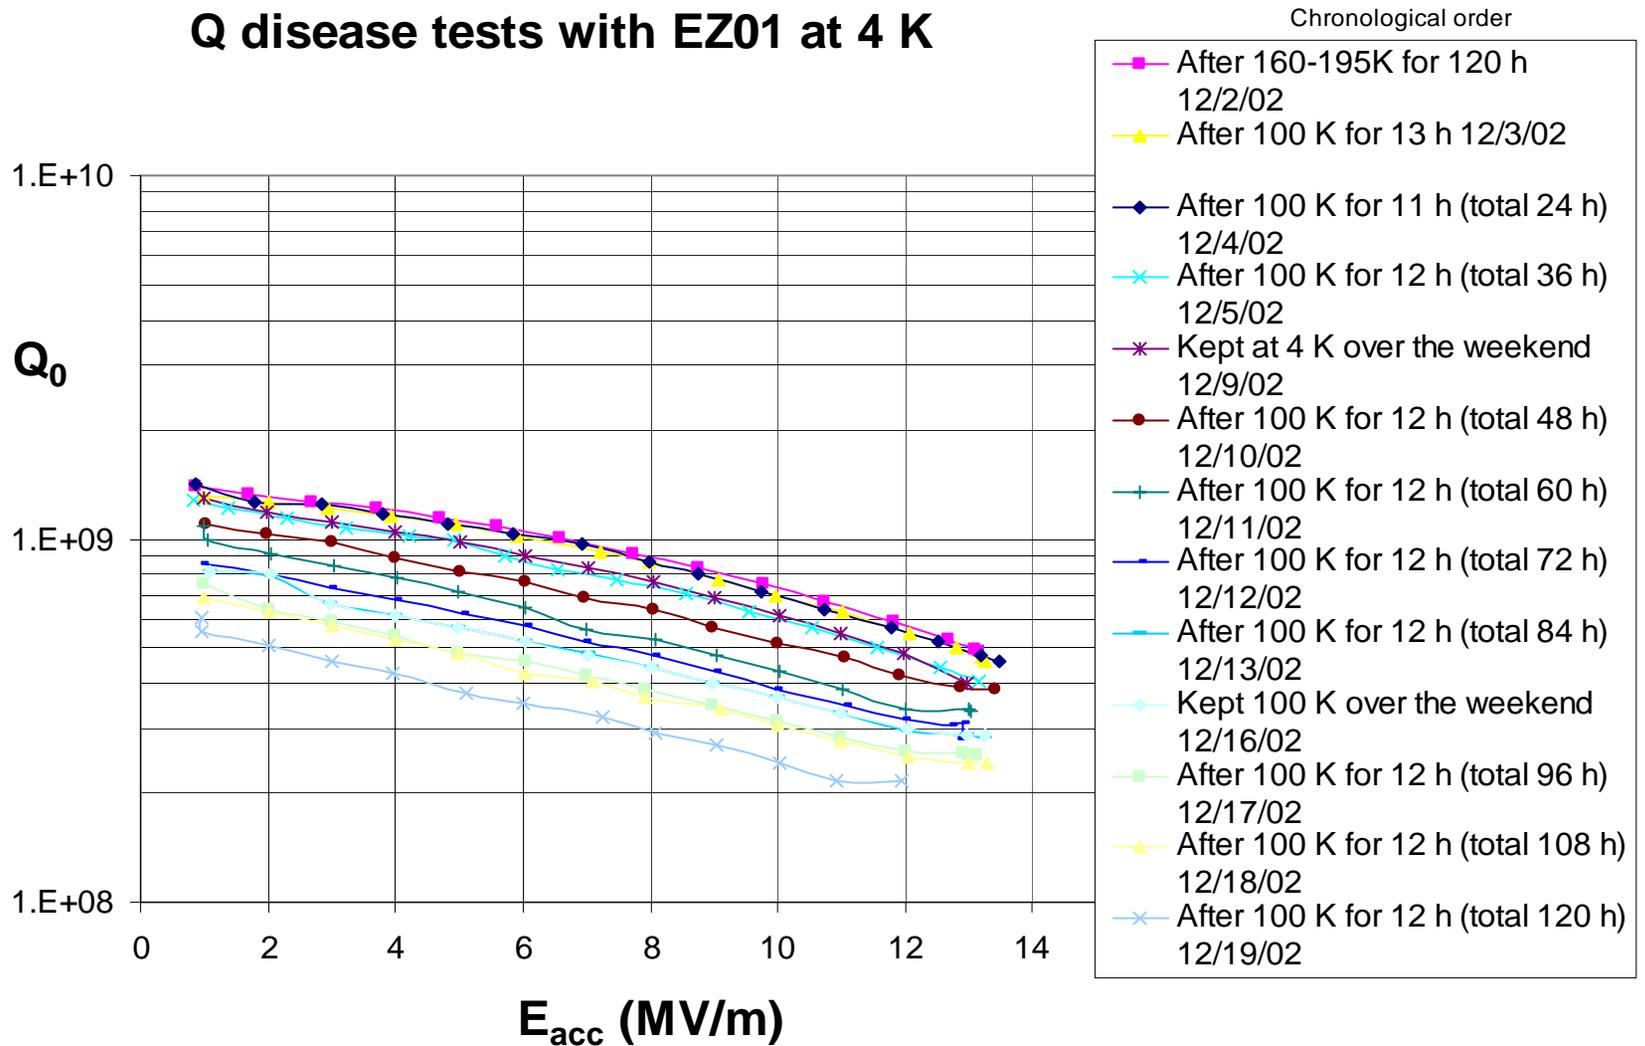

- What is the experimentally achievable  $H_p$  at 4 K? It has been  $\sim 1800$  Oe at 2 K with TESLA cavities. (Due to the better thermal conductivity of liquid He at  $T < 2.17$  K (Lambda point), it is expected that the achievable field is higher at 2 K. )
- Are there any difference between elliptical and spoke cavities in terms of the field limitations? It has been shown for spoke cavities that the maximum fields are almost the same at 4 K and 2 K, whereas some elliptical cavities have shown difference as much as a factor of 2.

# Q<sub>0</sub> disease tests

- Q<sub>0</sub> disease is a degradation of Q<sub>0</sub> due to niobium hydrides (T<sub>c</sub>~1.2 K?) caused by holding the cavity at medium temperatures (~100 K). It had been said before our tests that low frequency cavities (<500 MHz) do not show it.
- A systematic Q disease tests have been carried out with our 350 MHz spoke cavities
- Spoke cavities made of RRR~250 Nb.
- No high temperature heat treatment. (<150 °C)
- Standard BCP (HF:HNO<sub>3</sub>:H<sub>3</sub>PO<sub>4</sub>=1:1:2) ~150 μm at <15°C

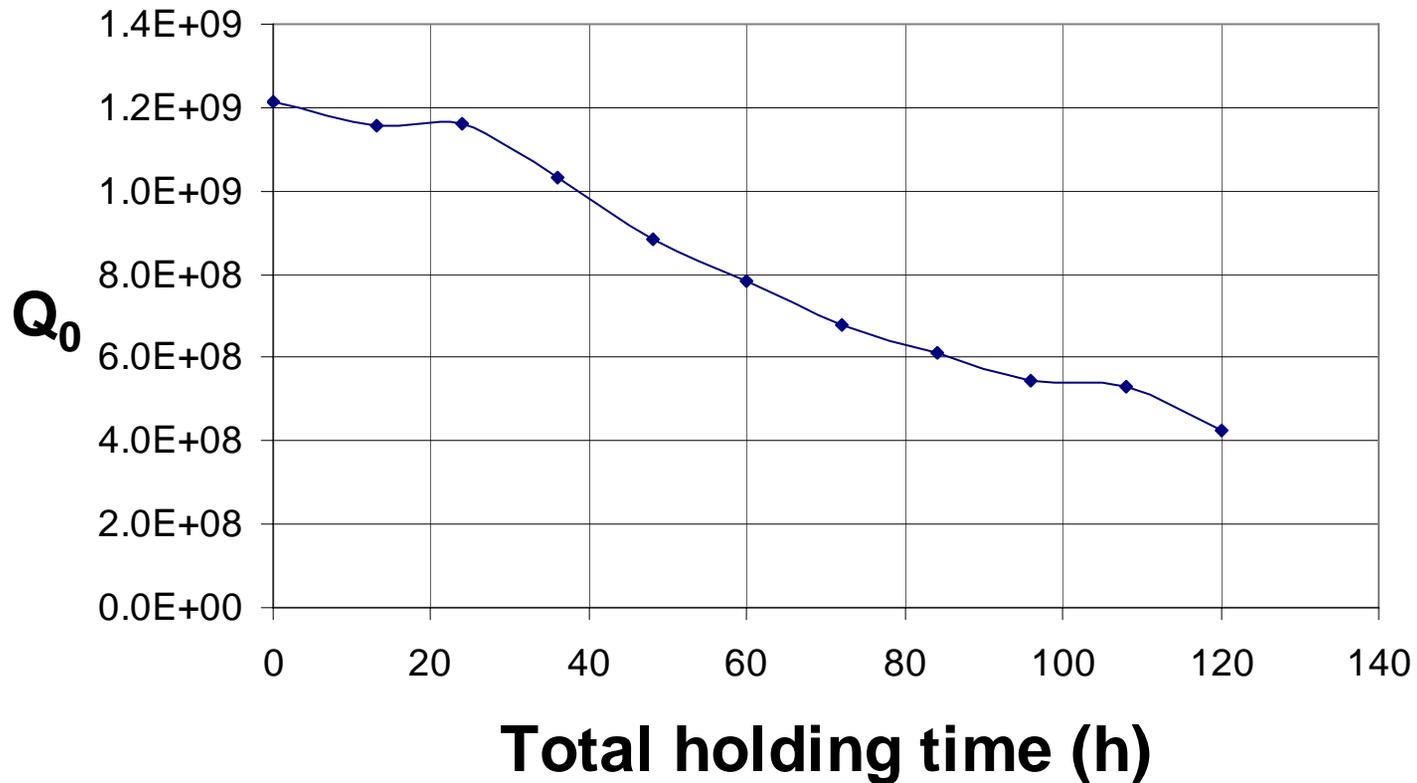

# $Q_0 - E_{acc}$ Curves During the Tests

Q disease tests with EZ01 at 4 K

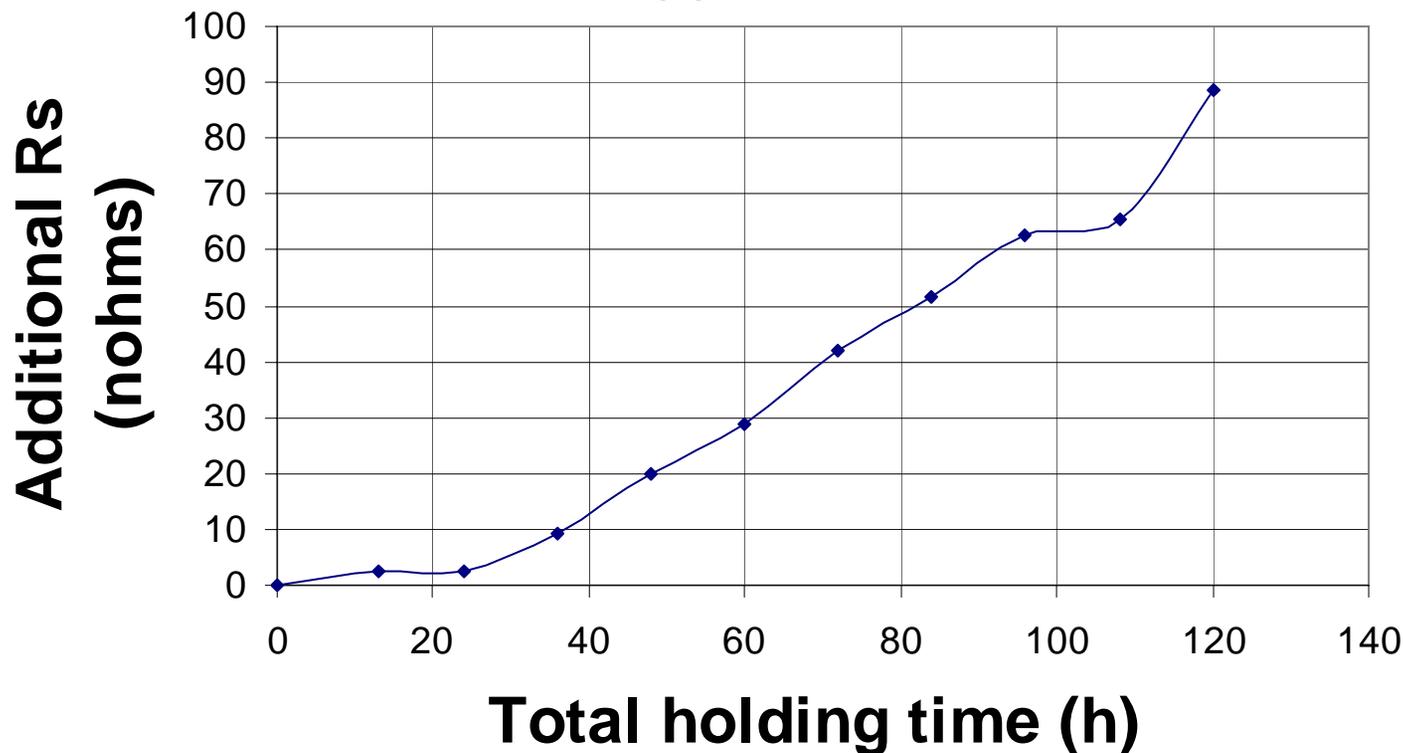

# $Q_0$ Dependence on the Holding Time at 100 K

## $Q_0$ vs holding time at 100 K

# Additional Surface Resistance Due to Q disease

Increase of surface resistance ( $R_s$ ) due to Q disease vs holding time at 100 K

# Summary of the Q disease tests

- With our 350-MHz spoke cavities, little Q disease occurs after 150- $\mu\text{m}$  BCP, up to  $\sim 24$  hours of holding time at  $\sim 100$  K.
- Holding the cavity for longer time causes Q disease.
- The additional surface resistance due to the Q disease increases linearly after the increase starts.
- Q disease disappears if the cavity is warmed up to 180 K. From what temperature this effect occurs needs to be determined.

# 3. High- $T_c$ Materials Study for RF Cavities

- Motivation
  - Reduction of construction and operation cost of particle accelerators is unavoidable for future projects !!
  - Although Nb cavities have reduced costs significantly, present accelerator costs are still too high to be easily funded.
  - High- $T_c$  materials could further reduce the costs.

# Problems with Bulk-Nb cavities

- Expensive material (price similar to Silver).
- Fabrication cost is much higher than copper cavities.
- Predicted theoretical limit of accelerating gradient ( $E_{acc}$ ) is  $\sim 50$  MV/m based on the theoretical critical magnetic field ( $H_c$ ) of  $\sim 2000$  Oe and the ratio of  $H_c/E_{acc} \sim 40$  Oe/(MV/m).
- Experimentally,  $\sim 1750 \pm 100$  Oe has been shown to limit the performance.
- State-of-the-art cavities have already shown the performance close to the limit, i.e., no further improvement of  $E_{acc}$ . (Lowering the  $H_c/E_{acc}$  can improve the  $E_{acc}$ , but  $\sim 35$  Oe/MV/m seems to be the limit.)
- Need to use expensive liquid helium (4K at atmospheric pressure) to cool the cavities since the Nb transition temperature ( $T_c$ ) is 9.2 K.
- Need to even lower the liquid helium temperature from 4K to  $\sim 2$ K for cavities at frequencies of  $>500$  MHz to reduce the BCS surface loss to be within the refrigerator's manageable level. This leads to a much more complicated and expensive refrigeration system.
- Need to shield ambient magnetic field to  $<10$  mG ( $<2$  mG for ILC) level to keep the RF surface loss sufficiently low.

It is a breakthrough if one can find a solution to these problems !!

# How can we solve these problems?

- Most of the problems can be solved by coating a high- $T_c$  material on a cheap metal such as copper. (Achievable  $E_{acc}$  is unknown.)
- But, unfortunately, it has been shown that the so-called high- $T_c$  materials that has  $T_c > 77K$  (liquid nitrogen) such as YBCO cannot be used since the RF surface resistance increases rapidly with higher magnetic field or  $E_{acc}$ .

# Present Candidates

- $\text{Nb}_3\text{Sn}$  ( $T_c=18\text{K}$ )

This has been studied until ~1996 for many years and has demonstrated some success with a few single-cell cavities, but experimental studies have shown lower critical magnetic field compared to Nb and difficulty in making uniform high-quality film. We have not studied this material yet. It might be just engineering of how to coat the cavity.

- $\text{MgB}_2$  ( $T_c=39\text{K}$ )

We started evaluating this material in 2003. See below.

Theoretical Limit Based on Superheating Critical Field.  
(These do not match experimental results, although experiments are difficult at high fields.)

$$H_p/E_{acc}=40 \text{ (Oe/MV/m)}$$

<b>Material</b>	<b>Operation Temp. [K]</b>	<b>Theoretical Limit <math>E_{acc}</math> [MV/m]</b>
Nb	4	49
Nb <sub>3</sub> Sn	4	95
MgB <sub>2</sub>	4	80
MgB <sub>2</sub>	20	52

# Magnesium Diboride ( $\text{MgB}_2$ )

- This material is readily available, but its superconductivity at 39K was found relatively recently (2001).
- A number of studies on this material has been done since then and it was found that the loss at higher magnetic field is much less than other high- $T_c$  materials.
- Measurements at LANL have shown that the BCS resistance at 4 K is about one order of magnitude lower than Nb.
- It has also been shown that this can be coated in much simpler fashion compared to other high- $T_c$  materials such as YBCO, which would lead to less cost.
- Coating on various substrates seems possible without degrading the quality.

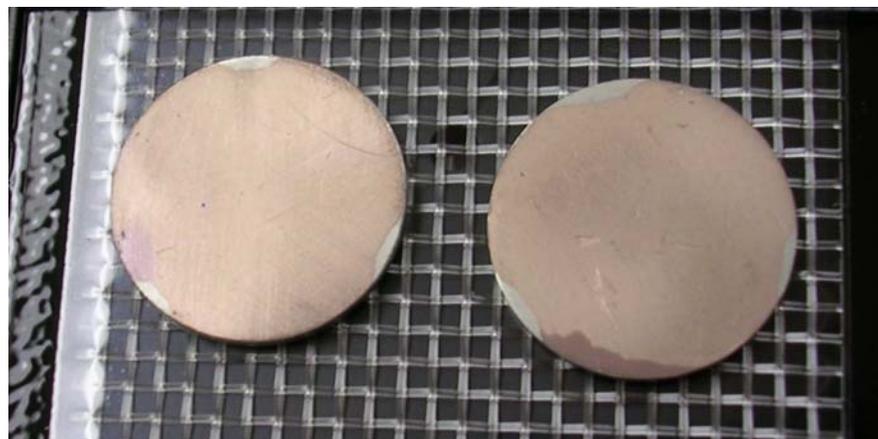

# Bulk and Film Samples We Tested

Bulk sample made by HIP at UCSD

25.0 mm in diameter and 4.60 mm in thickness after polishing the surface with a 0.1- $\mu\text{m}$  diamond lapping film. A reflection of 3 fluorescent lights is seen on the surface.

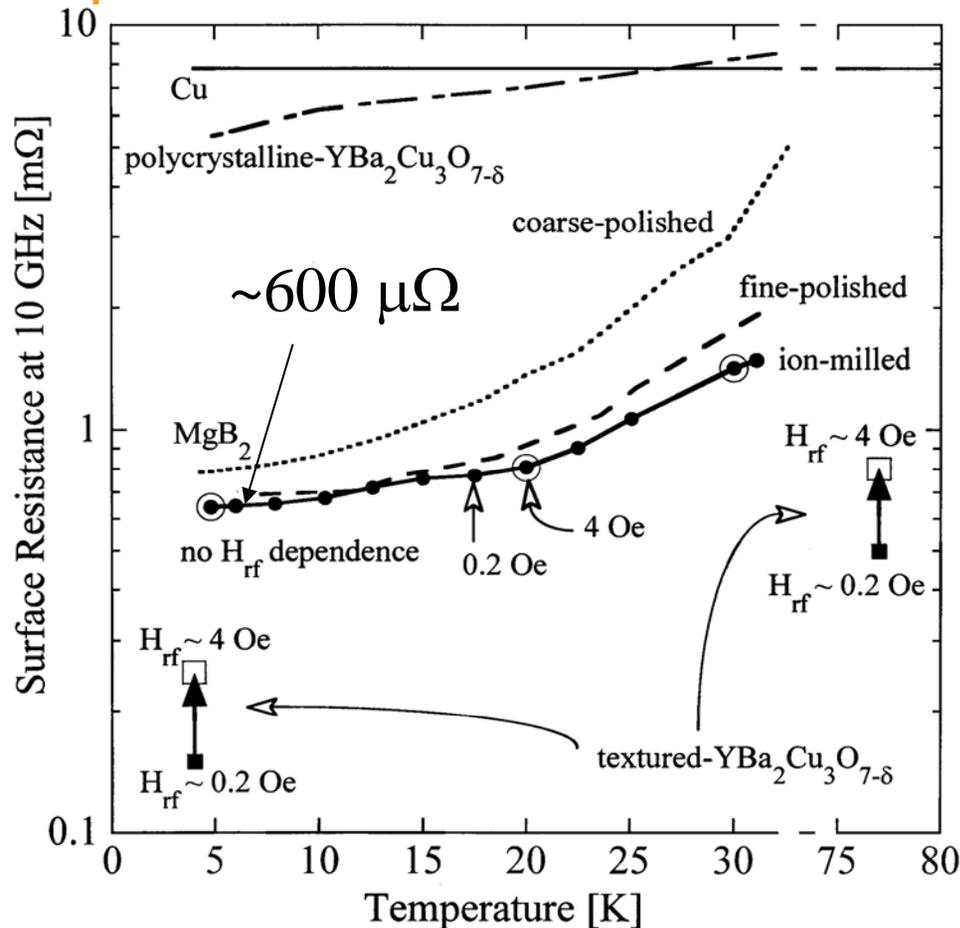

400 nm film on Nb coated at STI

Diameter: 14.6 mm  
Substrate: 1 mm Nb

Films coated on 1 cm<sup>2</sup> sapphire  
are not shown here.

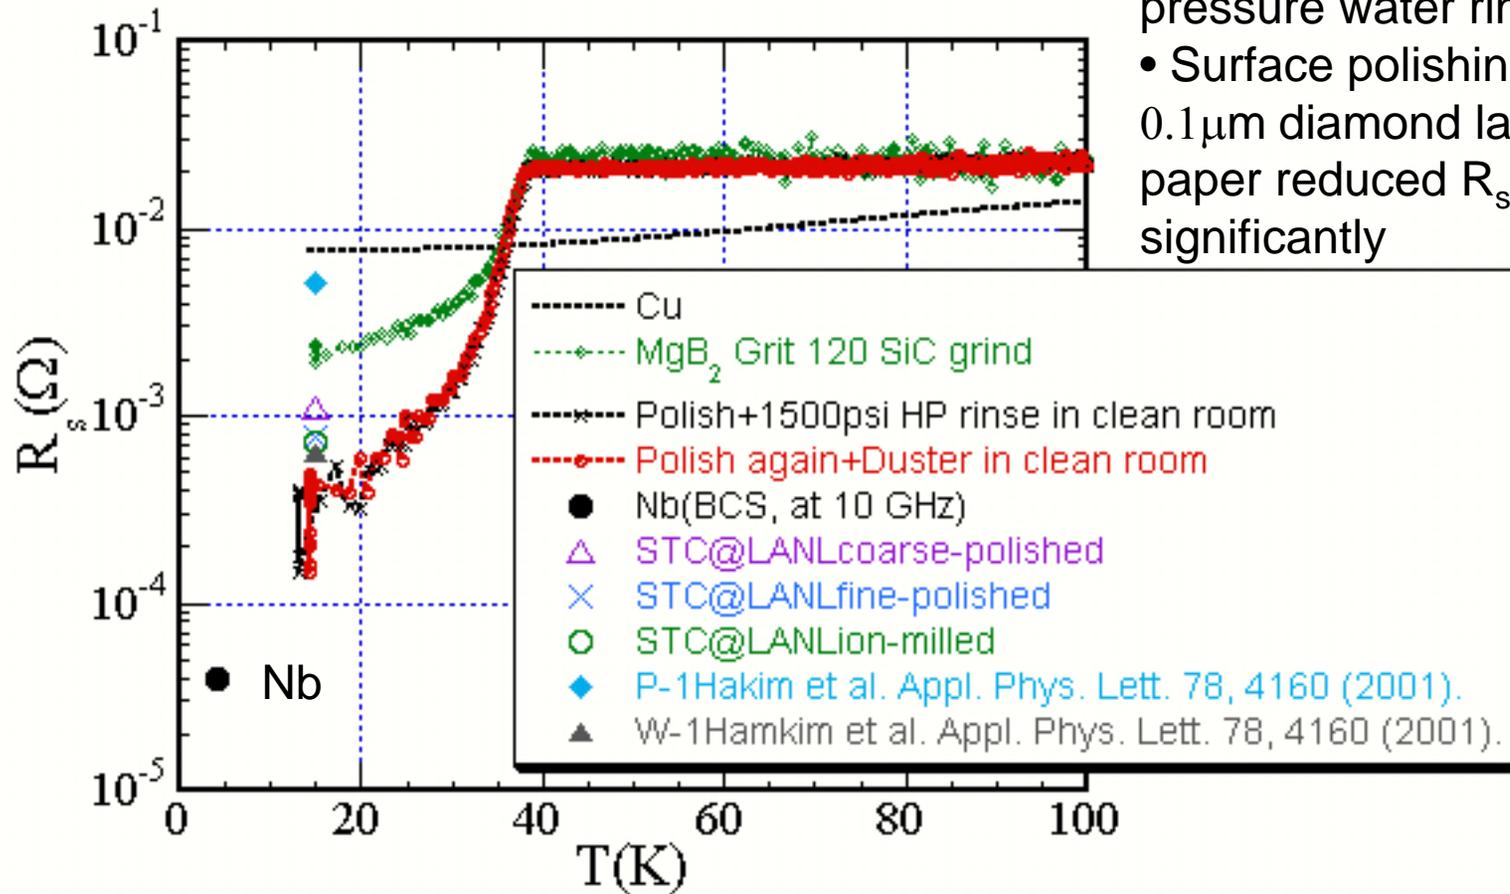

# First RF Surface Resistance Measurement of HIP Bulk Sample at STC of LANL

- No increase of  $R_s$  from 0.2 to 4 Oe as compared to significant increase with YBCO.
- This material is not optimized for low  $R_s$ , i.e., there is room for improvement
- $R_s$  (BCS) of Nb (4K, 10 GHz)  $\sim 40 \mu\Omega$

Alp Findikoglu et al. (Superconductivity Technology Center at LANL), Applied Physics Letters 83 108 (2003).

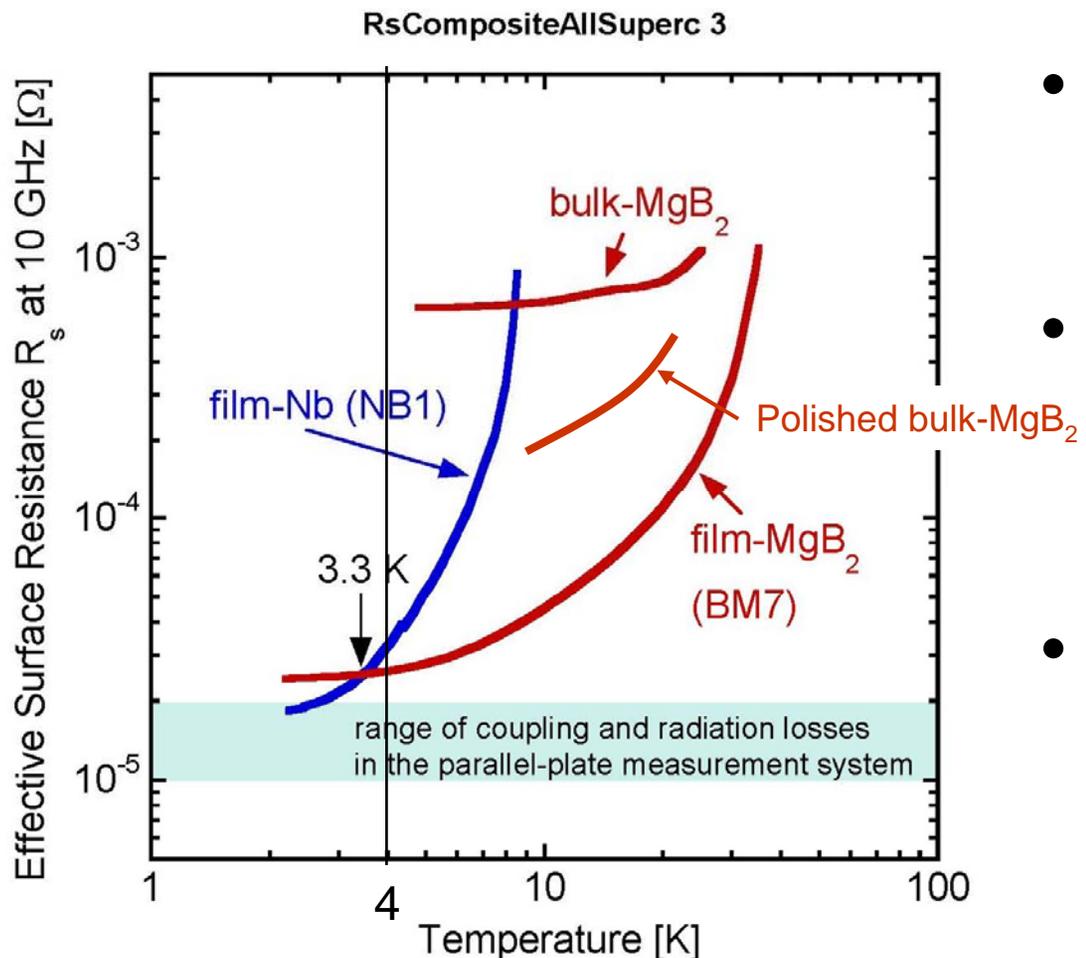

# RF Surface Resistance Measurement of HIP Bulk $\text{MgB}_2$ at LANSCE of LANL: Results Converted to 10 GHz

- No degradation with high-pressure water rinse
- Surface polishing with  $0.1\mu\text{m}$  diamond lapping paper reduced  $R_s$  significantly

T. Tajima, J. Liu et al., 6<sup>th</sup> European Conference of Applied Superconductivity, Sorrento, September 14-18

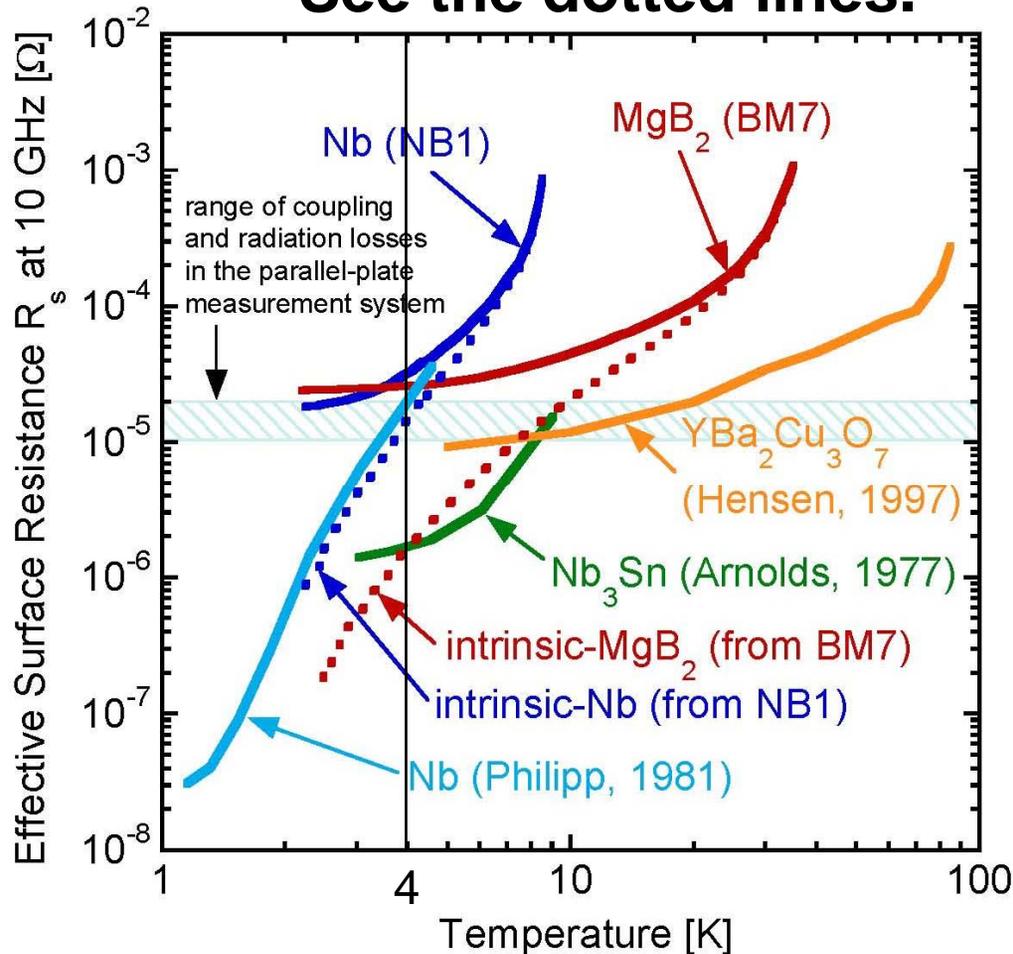

400 nm film on 1 cm<sup>2</sup> sapphire substrate showed further  $R_s$  reduction, lower than Nb at 4 K!!

- Data taken by Alp Findikoglu of STC at LANL, unpublished
- Film prepared by Brian Moeckly of Superconductor Technologies, Inc.
- Polycrystal, non-epitaxial film

Intrinsic (BCS) Resistance could be about one order of magnitude lower than Nb at 4 K!!

See the dotted lines.

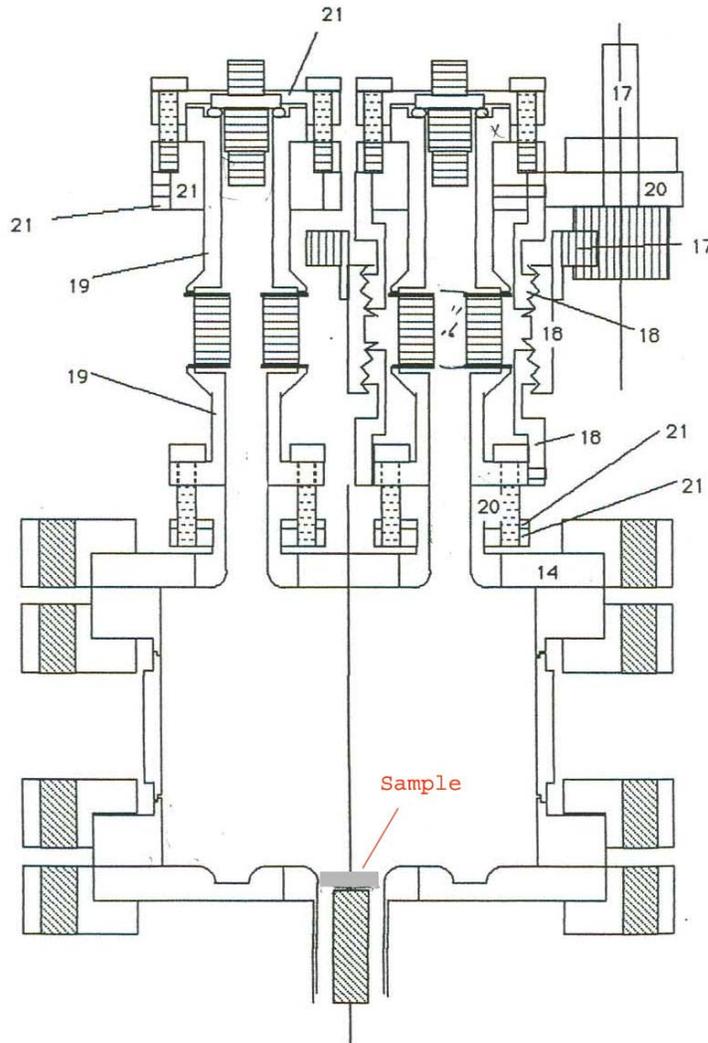

Alp Findikoglu of  
STC at LANL,  
unpublished

# $R_s$ Dependence on Magnetic Field was measured in collaboration with Cornell

- This measurement is critical to determine the feasibility of materials for accelerator applications.
- We placed a  $MgB_2$  coated Nb disk in a  $TE_{011}$  mode cavity and measured cavity  $Q_0$  which is inversely proportional to  $R_s$ .
- We increased the magnetic field up to available limit and measured the change of  $Q_0$ .
- Measured at 4K so that Nb is superconducting, which makes the measurement more sensitive to the  $R_s$  change of  $MgB_2$  than using Cu cavity.

# Tests at Cornell with 6-GHz Nb $TE_{011}$ Cavity

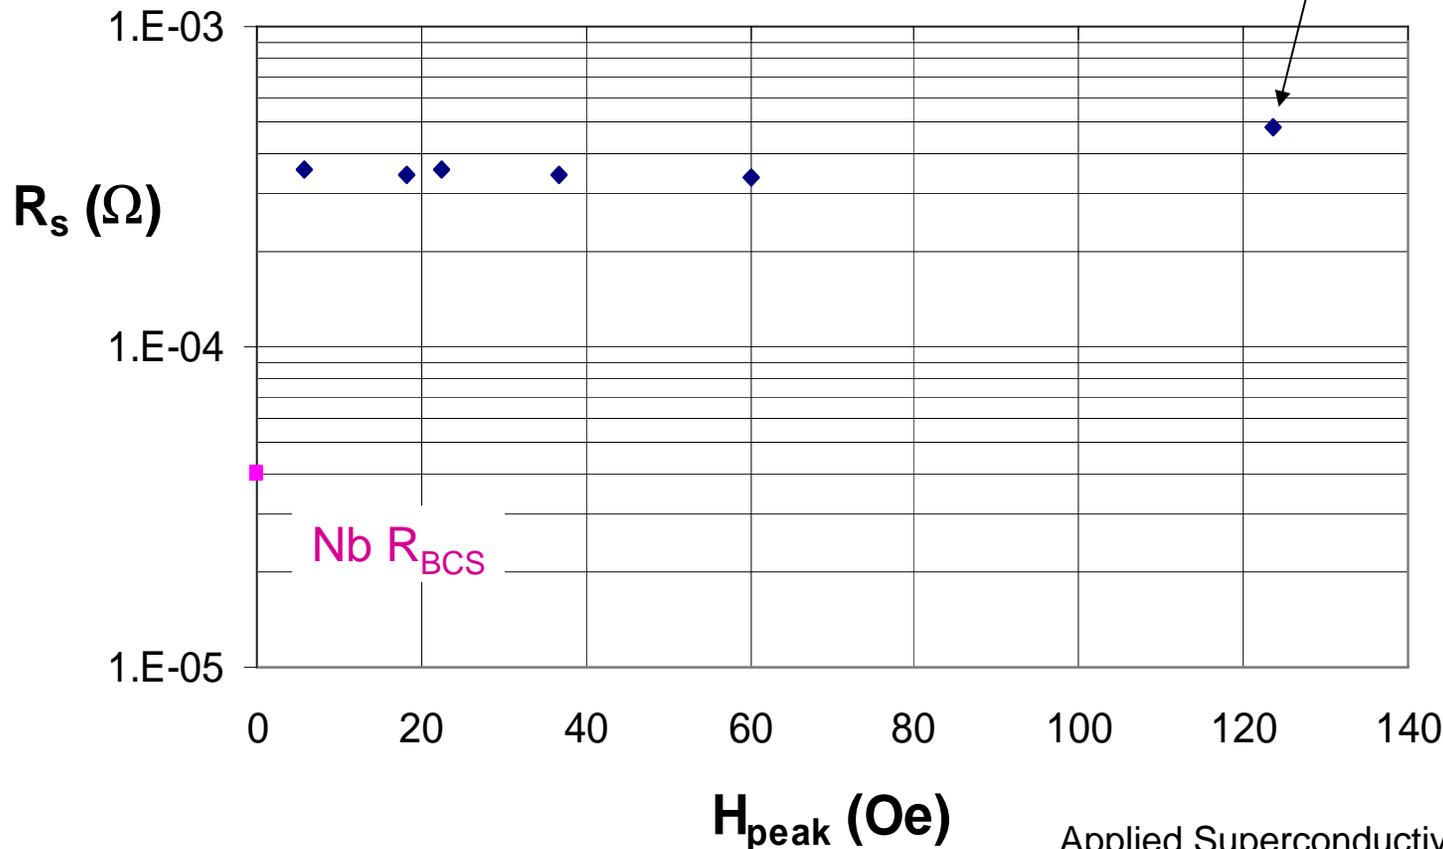

Measurements in collaboration  
with Cornell personnel  
Alexander Romanenko, Hasan  
Padamsee

# Results showed little increase of $R_s$ up to $\sim 120$ Oe, available power !

$R_s$  vs  $H_{\text{peak}}$  at 10 GHz

Heating due to bad cooling?

As you can see, the film quality is not good.

It may be due to the surface roughness. (The substrate Nb was not polished.)

Applied Superconductivity Conf., Oct., 2004

# Future Plans for MgB<sub>2</sub> Study

- Continue power dependence tests with better films and coating on copper at higher magnetic fields.
- Develop methods for coating on inner surfaces of elliptical cavities and other shapes.
- Evaluate the quality of the films and try to coat existing small ( $\sim 3$  GHz) elliptical single-cell cavities and take  $Q_0 - E_{\text{acc}}$  curves.
- In parallel, test the critical magnetic field with short pulses ( $< 1 \mu\text{s}$ ) at SLAC to avoid heating effect at high magnetic fields.
